2/35

Classification of PDE

- PDEs are very common in engineering applications.
- Before we attempt to solve these equations numerically, we will learn to classify the PDEs
- The need for classification arises from the need to determine the method of solution
- We can get very wrong solutions, when a wrong approach is used
- Generally, the classification is carried out by using the Characteristics Method
- We shall see discuss it now

8:57 AM

3/35

Concept of Characteristics-I

- Consider a simple PDE called the Convection Equation given by

$$\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} = 0 \quad (1)$$

$u = \text{constant}$

- Let the initial condition at $t = 0$, $T(0, x)$ be $F(x)$
- The analytical solution at any given $T(t, x) = F(x - ut)$
- This can be verified as follows. Note that F is only a function of x . On substitution, of the solution into the LHS of the PDE we get,

$$\left. \frac{dF}{dx} \right|_{(x-ut)} \frac{\partial (x - ut)}{\partial t} + u \left. \frac{dF}{dx} \right|_{(x-ut)} \frac{\partial (x - ut)}{\partial x}$$

$$\left. \frac{dF}{dx} \right|_{(x-ut)} (-u) + u \left. \frac{dF}{dx} \right|_{(x-ut)}$$

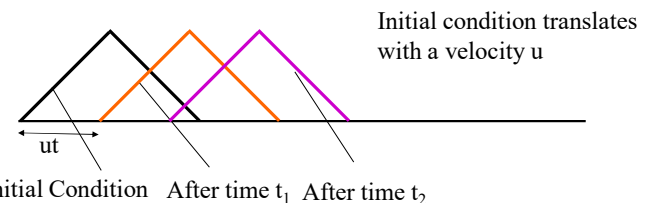

Hence OK

8:57 AM

4/35

Concept of Characteristics-II

- To appreciate the solution graphically let us refer to the figure shown below

- Since $T = T(x, t)$, using chain rule assuming continuity of T , we can write

$$dT = \frac{\partial T}{\partial t} dt + u \frac{\partial T}{\partial x} dx \quad (2)$$

8:57 AM

Concept of Characteristics-III

5/35

- Eqs. (1) and (2) can be viewed as two simultaneous equations for the partial derivatives as given by

$$\begin{bmatrix} 1 & u \\ dt & dx \end{bmatrix} \begin{Bmatrix} T_t \\ T_x \end{Bmatrix} = \begin{Bmatrix} 0 \\ dT \end{Bmatrix}$$

- For unique solutions of T_t and T_x the necessary condition is

$$\begin{vmatrix} 1 & u \\ dt & dx \end{vmatrix} \neq 0$$

- Discontinuities in the slopes are possible, if

$$\begin{vmatrix} 1 & u \\ dt & dx \end{vmatrix} = 0 \quad \text{Or when} \quad \frac{dt}{dx} = \frac{1}{u} \quad (3)$$

8:57 AM

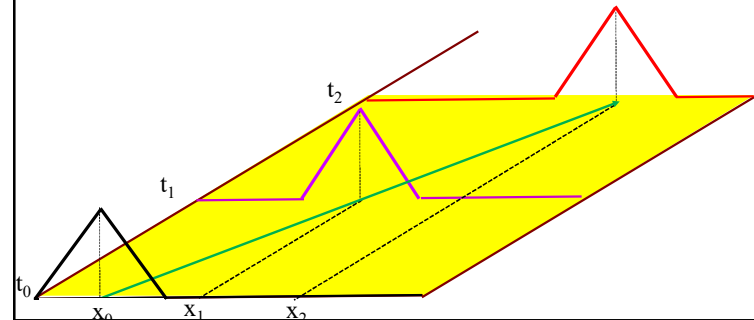

Concept of Characteristics-IV

6/35

- Eq. (3) when separated and integrated with an initial condition of $x = x_0$ at $t = t_0$ will give,

$$x = x_0 + u(t - t_0) \quad (4)$$

- The state of fluid in t, x plane can be visualised as follows

8:57 AM

Concept of Characteristics-V

7/35

- From the previous slide, we have realized that Eq. (2) and its integrated form in Eq. (4) describes the path along which the discontinuities can propagate
- This is called the **Characteristic Direction**
- The speed of propagation of the discontinuity is given by

$$\frac{dx}{dt} = \frac{u}{1} = u$$

- Equations that have real characteristic direction are called **Hyperbolic Equations** (Propagation type)
- Thus, convection equation is a hyperbolic equation

8:57 AM

Concept of Characteristics-VI

8/35

- If instead of Eq. (1), if we would have had the governing equation as

$$A \frac{\partial T}{\partial t} + B \frac{\partial T}{\partial x} = 0$$

- By analogy, the characteristic direction would have been by

$$\frac{dx}{dt} = \frac{B}{A} = - \frac{\frac{\partial T}{\partial t}}{\frac{\partial T}{\partial x}} = \lambda \quad \text{Usually denoted by } \lambda$$

- Thus, λ is obtained by solving the equation

$$B - \lambda A = 0 \quad (5)$$

8:57 AM Concept of Characteristics-VII 9/35

- Now we will extend it to a set of first order equations
- The motivation arises from the fact that compressible flows are governed by this type of equations
- We shall start from the most general form. It is convenient to work with the matrix notation

$$\begin{bmatrix} a_1 & a_2 \\ b_1 & b_2 \end{bmatrix} \frac{\partial}{\partial t} \begin{Bmatrix} f \\ g \end{Bmatrix} + \begin{bmatrix} a_3 & a_4 \\ b_3 & b_4 \end{bmatrix} \frac{\partial}{\partial x} \begin{Bmatrix} f \\ g \end{Bmatrix} = \begin{Bmatrix} a_5 \\ b_5 \end{Bmatrix}$$

$$[A] \frac{\partial}{\partial t} \begin{Bmatrix} f \\ g \end{Bmatrix} + [B] \frac{\partial}{\partial x} \begin{Bmatrix} f \\ g \end{Bmatrix} = \{S\}$$

- If we compare this with our example for one variable, the equation is identical except for the fact that the coefficients A and B are now matrices and the variable T has become a vector f and g

8:57 AM Concept of Characteristics-VIII 10/35

- The characteristic directions in this case is given by solving

$$\frac{dx}{dt} = \frac{[B]}{[A]} = \lambda$$

$$\text{Or } [B] - \lambda[A] = 0$$

8:57 AM Concept of Characteristics-IX 11/35

- To consider a concrete example, we shall take a set called the water hammer equation given by the set

$$\frac{1}{a^2} \frac{\partial p}{\partial t} + \frac{u}{a^2} \frac{\partial p}{\partial x} + \rho \frac{\partial u}{\partial x} = 0 \quad \text{Mass Balance}$$

$$\rho \frac{\partial u}{\partial t} + \rho u \frac{\partial u}{\partial x} + \frac{\partial p}{\partial x} = 0 \quad \text{Momentum Balance}$$

- The above two equations can be recast as

$$\begin{bmatrix} 0 & \frac{1}{a^2} \\ \rho & 0 \end{bmatrix} \frac{\partial}{\partial t} \begin{Bmatrix} u \\ p \end{Bmatrix} + \begin{bmatrix} \rho & \frac{u}{a^2} \\ \rho u & 1 \end{bmatrix} \frac{\partial}{\partial x} \begin{Bmatrix} u \\ p \end{Bmatrix} = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix}$$

8:57 AM Concept of Characteristics-X 12/35

$$[B] - \lambda[A] = 0$$

$$\Rightarrow \begin{bmatrix} \rho & \frac{u}{a^2} \\ \rho u & 1 \end{bmatrix} - \lambda \begin{bmatrix} 0 & \frac{1}{a^2} \\ \rho & 0 \end{bmatrix} = 0$$

$$\Rightarrow \begin{vmatrix} \rho & \frac{u-\lambda}{a^2} \\ \rho(u-\lambda) & 1 \end{vmatrix} = 0 \quad \Rightarrow \rho = \rho \frac{(u-\lambda)^2}{a^2}$$

$$\Rightarrow (u-\lambda) = \pm a \quad \Rightarrow \lambda = u \pm a = \frac{dx}{dt}$$

Thus the set is hyperbolic

- In general, the first order set in TFE are hyperbolic equations and we shall look at their solutions later

8:57 AM **Concept of Characteristics-XI** 13/35

- We can now extend this to second order PDEs. Consider a general second order equation

$$Af_{xx} + Bf_{xy} + Cf_{yy} + Df_x + Ef_y + F = 0$$

- Also by chain rule we can write.

$$d(f_x) = f_{xx}dx + f_{xy}dy$$

$$d(f_y) = f_{yx}dx + f_{yy}dy$$

- In matrix form, we can write

$$\begin{bmatrix} A & B & C \\ dx & dy & 0 \\ 0 & dx & dy \end{bmatrix} \begin{Bmatrix} f_{xx} \\ f_{xy} \\ f_{yy} \end{Bmatrix} = \begin{Bmatrix} -Df_x - Ef_y - F \\ d(f_x) \\ d(f_y) \end{Bmatrix}$$

8:57 AM **Concept of Characteristics-XII** 14/35

- For multiple solutions for f_{xx} , f_{xy} and f_{yy}

$$\begin{vmatrix} A & B & C \\ dx & dy & 0 \\ 0 & dx & dy \end{vmatrix} = 0$$

$$\Rightarrow A dy^2 - B dx dy + C dx^2 = 0$$

$$\Rightarrow A \left(\frac{dy}{dx} \right)^2 - B \frac{dy}{dx} + C = 0$$

$$\Rightarrow \frac{dy}{dx} = \frac{B \pm \sqrt{B^2 - 4AC}}{2A}$$

- The nature of characteristic direction will depend on the nature of discriminant

8:57 AM **Concept of Characteristics-XIII** 15/35

For $B^2 - 4AC > 0$ Roots real, hence **Hyperbolic**

For $B^2 - 4AC = 0$ Roots real, but repeated **Parabolic**

For $B^2 - 4AC < 0$ Roots imaginary, hence **Elliptic**

- We shall get to more details when we solve them later

8:57 AM **Consistency-I** 16/35

- A finite difference scheme solving a given PDE is said to be consistent, if when Δt and Δx are allowed to approach zero, the approximate solution will approach the exact solution of the PDE
- Consistency of a scheme can be checked by application of Taylor series
- Let us consider an example for illustration

8:57 AM

17/35

Consistency-II

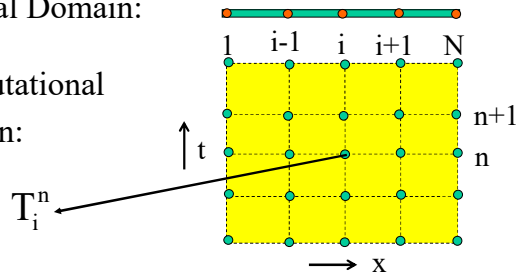

Consider transient conduction in a rod

Governing Equation: $\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}$

Physical Domain:

Computational

Domain:

8:57 AM

18/35

Consistency-III

- One of the FDM approximation is FTCS

$$\left. \frac{\partial T}{\partial t} \right|_i^n = \frac{T_i^{n+1} - T_i^n}{\Delta t} \quad \left. \frac{\partial^2 T}{\partial x^2} \right|_i^n = \frac{T_{i+1}^n - 2T_i^n + T_{i-1}^n}{\Delta x^2}$$

- This leads to the nodal equation

$$T_i^{n+1} = T_i^n + \frac{\alpha \Delta t}{\Delta x^2} (T_{i+1}^n - 2T_i^n + T_{i-1}^n)$$

8:57 AM

19/35

Consistency-IV

- Using Taylor series, we can write the following:

$$T_i^{n+1} = T_i^n + \left. \frac{\partial T}{\partial t} \right|_i^n \Delta t + \frac{\left. \frac{\partial^2 T}{\partial t^2} \right|_i^n}{2!} \frac{\Delta t^2}{2!} + \frac{\left. \frac{\partial^3 T}{\partial t^3} \right|_i^n}{3!} \frac{\Delta t^3}{3!} + \text{HOT}$$

- Similarly, we can write

$$T_{i\pm 1}^n = T_i^n \pm \left. \frac{\partial T}{\partial x} \right|_i^n \Delta x + \frac{\left. \frac{\partial^2 T}{\partial x^2} \right|_i^n}{2!} \frac{\Delta x^2}{2!} \pm \frac{\left. \frac{\partial^3 T}{\partial x^3} \right|_i^n}{3!} \frac{\Delta x^3}{3!} + \text{HOT}$$

- The above can be modified as

$$\frac{T_{i+1}^n + T_{i-1}^n - 2T_i^n}{\Delta x^2} = 2 \left. \frac{\partial^2 T}{\partial x^2} \right|_i^n \frac{1}{2!} + 2 \left. \frac{\partial^4 T}{\partial x^4} \right|_i^n \frac{\Delta x^2}{4!} + \text{HOT}$$

8:57 AM

20/35

Consistency-V

- Substituting these in our nodal equation, we get

$$T_i^n + \left. \frac{\partial T}{\partial t} \right|_i^n \Delta t + \frac{\left. \frac{\partial^2 T}{\partial t^2} \right|_i^n}{2!} \frac{\Delta t^2}{2!} + O(\Delta t^3) = T_i^n + \alpha \Delta t \left(\left. \frac{\partial^2 T}{\partial x^2} \right|_i^n + 2 \left. \frac{\partial^4 T}{\partial x^4} \right|_i^n \frac{\Delta x^2}{4!} + O(\Delta x^4) \right)$$

- Cancelling T_i^n from both sides and then dividing both sides by Δt and finally allowing Δt and Δx approach 0, we get the exact original equation hence consistent

8:57 AM

21/35

Consistency-VI

For finite values of Δt and Δx we are actually solving a different PDE. This is called Modified PDE or MPDE

The equation in the previous slide can be written as

$$\frac{\partial T}{\partial t} + O(\Delta t) = \alpha \frac{\partial^2 T}{\partial x^2} + O(\Delta x^2)$$

The **leading truncation error** for the approximation used is also included.

Thus, the scheme is said to be **First order accurate in time and Second order accurate in space**.

8:57 AM

22/35

Inconsistency (an example)-I

- Consider, Convection Equation $\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} = 0$
- Modelling by Lax Scheme

$$\left. \frac{\partial T}{\partial t} \right|_i^n = \frac{T_i^{n+1} - 0.5(T_{i+1}^n + T_{i-1}^n)}{\Delta t} \quad \left. \frac{\partial T}{\partial x} \right|_i^n = \frac{T_{i+1}^n - T_{i-1}^n}{2\Delta x}$$

- Nodal Equation becomes

$$\frac{T_i^{n+1} - 0.5(T_{i+1}^n + T_{i-1}^n)}{\Delta t} + \frac{u(T_{i+1}^n - T_{i-1}^n)}{2\Delta x} = 0$$

$$T_i^{n+1} = 0.5(T_{i+1}^n + T_{i-1}^n) - \frac{u\Delta t}{2\Delta x}(T_{i+1}^n - T_{i-1}^n) \quad (6)$$

8:57 AM

23/35

Inconsistency (an example)-II

- From Taylor Series, we get

$$T_{i\pm 1}^n = T_i^n \pm \left. \frac{\partial T}{\partial x} \right|_i^n \Delta x + \frac{\partial^2 T}{\partial x^2} \Big|_i^n \frac{\Delta x^2}{2!} \pm \left. \frac{\partial^3 T}{\partial x^3} \right|_i^n \frac{\Delta x^3}{3!} + HOT$$

$$\Rightarrow T_{i+1}^n - T_{i-1}^n = 2 \left. \frac{\partial T}{\partial x} \right|_i^n \Delta x + 2 \left. \frac{\partial^3 T}{\partial x^3} \right|_i^n \frac{\Delta x^3}{3!} + HOT$$

$$And \quad T_{i+1}^n + T_{i-1}^n = 2T_i^n + 2 \left. \frac{\partial^2 T}{\partial x^2} \right|_i^n \frac{\Delta x^2}{2!} + O(\Delta x^4)$$

- Plugging the above in Eq. (6), we get

$$T_i^n + T_i^n \Delta t + T_i^n \frac{\Delta t^2}{2} + O(\Delta t^3) = T_i^n + T_{xx} \Big|_i^n \frac{\Delta x^2}{2} - \frac{u\Delta t}{\Delta x} \left(T_x \Big|_i^n \Delta x + O(\Delta x^3) \right) \quad (7)$$

8:57 AM

24/35

Inconsistency (an example)-III

$$\Rightarrow T_i^n + O(\Delta t) + u \left(T_x \Big|_i^n + O(\Delta x^2) \right) = T_{xx} \Big|_i^n \frac{\Delta x^2}{2\Delta t}$$

- Hence, as Δt and Δx tend to zero, the RHS does not go to zero due the inconsistent term on the RHS
- It is interesting to note that as we reduce Δt to zero for a fixed Δx , the errors build, while for a given Δt , as we reduce Δx , the errors diminish and the method can behave consistently

8:57 AM

25/35

Inconsistency (Cont'd)

- We note that we get an indeterminate quantity, which depends on how the ratio of Δt and Δx approaches a limit
- For most propagation equations, we can convert higher order time derivatives into space derivatives
- For example, if we consider convection equation

$$T_{tt} = (T_t)_t = (-uT_x)_t = (-uT_t)_x = (-u(-uT_x))_x = u^2T_{xx}$$

- Thus, Eq. (7) can be written as

$$T_t + uT_x = 0.5 \frac{\Delta x^2}{\Delta t} T_{xx} - 0.5 \Delta t u^2 T_{xx} + \text{HOT}$$

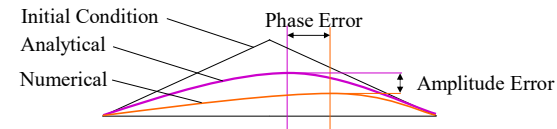

- Note that in MPDE given above, RHS has only spatial derivatives. This will be used later in analysing errors

8:57 AM

26/35

Concepts in Numerical Errors

- Consider, Transport Equation $\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} = \alpha \frac{\partial^2 T}{\partial x^2}$

- **Causes:** Spurious derivatives introduced due to truncation error
- **Terminology:** Numerical Dissipation
Numerical Dispersion

8:57 AM

27/35

Behaviour of Error

- Consider $\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}$
- Let error ε be defined as $\varepsilon = T_{\text{numerical}} - \bar{T}_{\text{exact}}$
- Numerical Solution actually solves for

$$\frac{\partial(\bar{T} + \varepsilon)}{\partial t} = \alpha \frac{\partial^2(\bar{T} + \varepsilon)}{\partial x^2}$$

$$\Rightarrow \frac{\partial(\bar{T})}{\partial t} + \frac{\partial(\varepsilon)}{\partial t} = \alpha \left(\frac{\partial^2(\bar{T})}{\partial x^2} + \frac{\partial^2(\varepsilon)}{\partial x^2} \right)$$

- The above implies that the error equation is identical to the original governing equation
- For problems with boundary values specified, error at boundaries will be zero

8:57 AM

28/35

Analytical Solution of Linear PDE

- Consider $\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}$ with $T(0, x) = \text{Sin}(\frac{\pi x}{L})$
and $T(t, 0) = T(t, L) = 0$

- Let Solution be of the form $T(t, x) = \hat{\varepsilon} e^{st} e^{ikx}$

$$\Rightarrow T_t = \hat{\varepsilon} s e^{st} e^{ikx} = sT \quad T_{xx} = \hat{\varepsilon} (ik)^2 e^{st} e^{ikx} = -k^2 T$$

- Substituting these in Gov. Eq., we get $s = -\alpha k^2$

- Thus, $T(t, x) = \hat{\varepsilon} e^{-\alpha k^2 t} e^{ikx}$

- From initial condition we get, $T(0, x) = \hat{\varepsilon} e^{ikx} = \text{Sin}(\frac{\pi x}{L})$

- By comparison, we can state that: $\hat{\varepsilon} = 1$, $k = (\frac{\pi}{L})$
and only imaginary part to be used

- Thus the solution is $T(t, x) = e^{-\alpha (\frac{\pi}{L})^2 t} \text{Sin}(\frac{\pi x}{L})$

8:57 AM

29/35

Analysis of Error Propagation

- Consider general purpose MPDE of the error equation

$$\frac{\partial(\varepsilon)}{\partial t} = \sum_{m=1}^{\infty} A_{2m} \frac{\partial^{2m}(\varepsilon)}{\partial x^{2m}} + \sum_{m=0}^{\infty} A_{2m+1} \frac{\partial^{2m+1}(\varepsilon)}{\partial x^{2m+1}}$$

- Substituting $\varepsilon = \hat{\varepsilon} e^{st} e^{ikx}$ we get

$$s \hat{\varepsilon} = \sum_{m=1}^{\infty} A_{2m} k^{2m} (-1)^m + \sum_{m=0}^{\infty} A_{2m+1} k^{2m+1} (-1)^m i$$

- In general, writing $s = \sigma + i\omega$ we get

$$\sigma = \sum_{m=1}^{\infty} A_{2m} k^{2m} (-1)^m \quad \text{and} \quad \omega = \sum_{m=0}^{\infty} A_{2m+1} k^{2m+1} (-1)^m$$

8:57 AM

30/35

Error Propagation (Cont'd)

- Substituting σ and ω in assumed form of Solution we get $\varepsilon(t, x) = \hat{\varepsilon} e^{\sigma t} e^{i(kx + \omega t)}$

$$\Rightarrow \varepsilon(t + \Delta t, x) = \hat{\varepsilon} e^{\sigma(t + \Delta t)} e^{i(kx + \omega(t + \Delta t))}$$

- Defining error amplification, G as,

$$G = \frac{\varepsilon(t + \Delta t, x)}{\varepsilon(t, x)} = e^{\sigma \Delta t} e^{i\omega \Delta t}$$

$$\Rightarrow |G| = e^{\sigma \Delta t} \quad \text{and} \quad \phi = \omega \Delta t$$

- Note that amplitude growth of error is from σ which is determined by coefficient of even derivatives and the phase error is from ω which is determined by coefficient of odd derivatives

8:57 AM

31/35

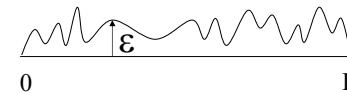

Stability Analysis

- If the magnitude of error amplification is greater than 1, then, error will explode
- It will be seen that most explicit methods employed for obtaining the solution tend to explode, when time step is too large.
- von Neumann stability analysis method is a simple and effective tool to identify the constraints on the time step

8:57 AM

32/35

von Neumann Stability Analysis

- Consider an arbitrary error distribution as shown
- From Fourier theory, we can decompose the error as

$$\varepsilon(x) = \frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos\left(\frac{m\pi x}{L}\right) + \sum_{m=1}^{\infty} b_m \sin\left(\frac{m\pi x}{L}\right)$$

- The above can be rewritten as

$$= \frac{a_0}{2} + \sum_{m=1}^{\infty} c_m e^{i \frac{m\pi x}{L}} + \sum_{m=1}^{\infty} c_{-m} e^{-i \frac{m\pi x}{L}}$$

8:57 AM

33/35

von Neumann Analysis (Cont'd)

- where $c_m = \frac{a_m - Ib_m}{2}$, $+c_{-m} = \frac{a_m + Ib_m}{2}$ and

$$I = \sqrt{-1}$$

- The equation can be compactly written as

$$\varepsilon(x) = \sum_{m=-\infty}^{\infty} c_m e^{I \frac{m\pi x}{L}}$$

- Stability would imply that none of the Fourier component would grow.
- It is illustrative to show the procedure with an example

8:57 AM

34/35

von Neumann Analysis (Example)

- Consider $\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2} \rightarrow \frac{\partial \varepsilon}{\partial t} = \alpha \frac{\partial^2 \varepsilon}{\partial x^2}$

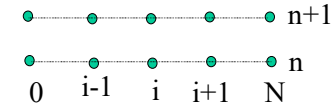

- Let the finite difference equation be

$$\varepsilon_i^{n+1} = \varepsilon_i^n + D(\varepsilon_{i+1}^n - 2\varepsilon_i^n + \varepsilon_{i-1}^n) \quad \text{where} \quad D = \frac{\alpha \Delta t}{\Delta x^2}$$

- Consider a Fourier component $\varepsilon_i^n = c_m e^{I \frac{m\pi x}{L}}$

- Since $x = i \Delta x$, $\varepsilon_i^n = c_m e^{I \frac{m\pi \Delta x}{L} i} = c_m e^{I i \theta_m}$

$$\text{where } \theta_m = \frac{m\pi \Delta x}{L}$$

8:57 AM

35/35

Example (Cont'd)

- Thus, $\varepsilon_i^n = c_m e^{I i \theta_m}$, $\varepsilon_{i\pm 1}^n = c_m e^{I(i\pm 1)\theta_m}$, $\varepsilon_i^{n+1} = G \varepsilon_i^n$

- Substitution of the above in the finite difference Eq.,

$$G c_m e^{I i \theta_m} = c_m e^{I i \theta_m} + D c_m e^{I i \theta_m} (e^{I \theta_m} - 2 + e^{-I \theta_m})$$

$$\Rightarrow G = 1 + D(2 \cos \theta_m - 2) = 1 + 2D(\cos \theta_m - 1)$$

- For stability $|G| \leq 1 \Rightarrow -1 \leq G \leq 1$

8:57 AM

36/35

Example (Cont'd)

$$G \leq 1$$

$$1 + 2D(\cos \theta_m - 1) \leq 1$$

$$2D(\cos \theta_m - 1) \leq 0$$

$$D \geq 0$$

$$-1 \leq G$$

$$-1 \leq 1 + 2D(\cos \theta_m - 1)$$

$$-2 \leq 2D(\cos \theta_m - 1)$$

$$D \leq \frac{1}{(1 - \cos \theta_m)}$$

$$\text{smallest value} \Rightarrow D \leq 0.5$$

- Thus for stability there is an upper bound on Δt
